# Programming Assignment 1: Learning Distributed Word Representations

Version: 1.2

#### **Changes by Version:**

- (v1.1)
  - 1. Part 1 Description: indicated that each word is associated with two embedding vectors and two biases
  - 2. Part 1: Updated calculate\_log\_co\_occurence to include the last pair of consecutive words as well
  - 3. Part 2: Updated question description for 2.1
  - 4. Part 4: Updated answer requirement for 4.1
  - 5. (1.3) Fixed symmetric GLoVE gradient
  - 6. (1.3) Clarified that W\_tilde and b\_tilde gradients also need to be implemented
  - 7. (2) Removed extra space leading up to docstring for compute\_loss\_derivative
- (v1.2)
  - 1. (1.4) Updated the training function train\_GLoVE to not use inplace update (e.g. W = W learning\_rate \* grad\_W instead), so the initial weight variables are not overwritten between asymmetric and symmetric GLoVE models.
  - 2. (2) Noted that <code>compute\_loss\_derivative</code> input argument <code>target\_mask</code> is 3D tensor with shape <code>[batch\_size x context\_len x 1]</code>

Version Release Date: 2021-01-27

Due Date: Thursday, Feb. 4, at 11:59pm

Based on an assignment by George Dahl

For CSC413/2516 in Winter 2021 with Professor Jimmy Ba and Professor Bo Wang

Submission: You must submit two files through MarkUs:

- 1. A PDF file containing your writeup, titled *a1-writeup.pdf*, which will be the PDF export of this notebook (i.e., by printing this notebook webpage as PDF). Your writeup must be typed. There will be sections in the notebook for you to write your responses. Make sure that the relevant outputs (e.g. print\_gradients() outputs, plots, etc.) are included and clearly visible.
- 2. This al-code ipynb iPython Notebook.

The programming assignments are individual work. See the Course Syllabus for detailed policies.

You should attempt all questions for this assignment. Most of them can be answered at least partially even if you were unable to finish earlier questions. If you think your computational results are incorrect, please say so; that may help you get partial credit.

The teaching assistants for this assignment are Harris Chan and Summer Tao. Send your email with subject "[CSC413] PA1" to mailto: csc413-2021-01-tas@cs.toronto.edu or post on Piazza with the tag pal.

#### Introduction

In this assignment we will learn about word embeddings and make neural networks learn about words. We could try to match statistics about the words, or we could train a network that takes a sequence of words as input and learns to predict the word that comes next.

This assignment will ask you to implement a linear embedding and then the backpropagation computations for a neural language model and then run some experiments to analyze the learned representation. The amount of code you have to write is very short but each line will require you to think very carefully. You will need to derive the updates mathematically, and then implement them using matrix and vector operations in NumPy.

### Starter code and data

First, perform the required imports for your code:

```
import collections
import pickle
import numpy as np
import os
from tqdm import tqdm
import pylab
from six.moves.urllib.request import urlretrieve
import tarfile
import sys

TINY = 1e-30
EPS = 1e-4
nax = np.newaxis
```

If you're using colaboratory, this following script creates a folder - here we used 'CSC413/A1' - in order to download and store the data. If you're not using colaboratory, then set the path to wherever you want the contents to be stored at locally.

store this notebook.

You can also manually download and unzip the data from [http://www.cs.toronto.edu/~jba/a1\_data.tar.gz] and put them in the same folder as where you

Feel free to use a different way to access the files data.pk, partially\_trained.pk, and raw\_sentences.txt.

The file *raw\_sentences.txt* contains the sentences that we will be using for this assignment. These sentences are fairly simple ones and cover a vocabulary of only 250 words (+ 1 special <code>[MASK]</code> token word).

```
# Setup working directory
# Change this to a local path if running locally
%mkdir -p /content/CSC413/A1/
%cd /content/CSC413/A1

```

We have already extracted the 4-grams from this dataset and divided them into training, validation, and test sets. To inspect this data, run the following:

Now data is a Python dict which contains the vocabulary, as well as the inputs and targets for all three splits of the data. data['vocab'] is a list of the 251 words in the dictionary; data['vocab'][0] is the word with index 0, and so on. data['train\_inputs'] is a 372,500 x 4 matrix where each row gives the indices of the 4 consecutive context words for one of the 372,500 training cases. The validation and test sets are handled analogously.

Even though you only have to modify two specific locations in the code, you may want to read through this code before starting the assignment.

### Part 1: GLoVE Word Representations (2pts)

In this part of the assignment, you will implement a simplified version of the GLoVE embedding (please see the handout for detailed description of the algorithm) with the loss defined as

$$L(\{\mathbf{w}_i, ilde{\mathbf{w}}_i, b_i, ilde{b}_i\}_{i=1}^V) = \sum_{i,j=1}^V (\mathbf{w}_i^ op ilde{\mathbf{w}}_j + b_i + ilde{b}_j - \log X_{ij})^2$$

•

Note that each word is represented by two d-dimensional embedding vectors  $\mathbf{w}_i$ ,  $\tilde{\mathbf{w}}_i$  and two scalar biases  $b_i$ ,  $\tilde{b}_i$ .

Answer the following questions:

### ▼ 1.1. GLoVE Parameter Count [0pt]

Given the vocabulary size V and embedding dimensionality d, how many parameters does the GLoVE model have? Note that each word in the vocabulary is associated with 2 embedding vectors and 2 biases.

1.1 **Answer**: Since the dimension of  $w_i$  and  $w_i$  are d and the dimension of the biases are 1, there are 2d+2 parameters to train for each vocabulary. Thus, we can get that the GLoVe model have

2V(d+1) trainable parameters.

# → 1.2. Expression for gradient $\frac{\partial L}{\partial \mathbf{w}_i}$ [1pt]

Write the expression for  $\frac{\partial L}{\partial \mathbf{w}_i}$ , the gradient of the loss function L with respect to one parameter vector  $\mathbf{w}_i$ . The gradient should be a function of  $\mathbf{w}, \tilde{\mathbf{w}}, b, \tilde{b}, X$  with appropriate subscripts (if any).

1.2 **Answer**: According to the given loss function, we can get  $\frac{\partial L}{\partial w_i}$  should be

$$egin{aligned} rac{\partial L}{\partial oldsymbol{w}_i} &= rac{\partial}{\partial oldsymbol{w}_i} \sum_{i,j=1}^V (oldsymbol{w}_i^T ilde{oldsymbol{w}}_i + b_i + ilde{b}_j - \log X_{ij})^2 \ &= 2 \sum_{i,j=1}^V (oldsymbol{w}_i^T ilde{oldsymbol{w}}_i + b_i + ilde{b}_j - \log X_{ij}) ilde{oldsymbol{w}}_i \end{aligned}$$

### ▼ 1.3. Implement the gradient update of GLoVE. [1pt]

See YOUR CODE HERE Comment below for where to complete the code

We have provided a few functions for training the embedding:

- calculate\_log\_co\_occurence computes the log co-occurrence matrix of a given corpus
- train GLoVE runs momentum gradient descent to optimize the embedding
- loss GLoVE:
  - $\circ$  INPUT V imes d matrix  $\mathbb{W}$  (collection of V embedding vectors, each d-dimensional); V imes d matrix  $\mathbb{W}_{ ext{tilde}}$ ; V imes 1 vector  $\mathbf{b}$  (collection of V bias terms); V imes 1 vector  $\mathbf{b}_{ ext{tilde}}$ ; V imes V log co-occurrence matrix.
  - OUTPUT loss of the GLoVE objective
- grad GLoVE: TO BE IMPLEMENTED.
  - INPUT:
    - $V \times d$  matrix  $\mathbb{V}$  (collection of V embedding vectors, each d-dimensional), embedding for first word;
    - $V \times d$  matrix  $\mathbb{V}$  tilde, embedding for second word;
    - $V \times 1$  vector b (collection of V bias terms);
    - V imes 1 vector b tilde, bias for second word;
    - $V \times V$  log co-occurrence matrix.
  - OUTPUT:
    - V imes d matrix  $\operatorname{grad}_{\mathbb{W}}$  containing the gradient of the loss function w.r.t.  $\mathbb{W}$ ;

- $lackbox{ } V imes d$  matrix  ${
  m grad}_{
  m W\_tilde}$  containing the gradient of the loss function w.r.t.  ${
  m W}_{
  m tilde}$ ;
- $V \times 1$  vector grad b which is the gradient of the loss function w.r.t. b.
- ullet V imes 1 vector <code>grad\_b\_tilde</code> which is the gradient of the loss function w.r.t. <code>b\_tilde</code>.

Run the code to compute the co-occurrence matrix. Make sure to add a 1 to the occurrences, so there are no 0's in the matrix when we take the elementwise log of the matrix.

```
vocab size = len(data['vocab']) # Number of vocabs
def calculate log co occurence (word data, symmetric=False):
    "Compute the log-co-occurence matrix for our data."
    log co occurence = np. zeros((vocab size, vocab size))
    for input in word data:
        # Note: the co-occurence matrix may not be symmetric
        \log \operatorname{co} \operatorname{occurence}[\operatorname{input}[0], \operatorname{input}[1]] += 1
        log co occurence[input[1], input[2]] += 1
        log co occurence[input[2], input[3]] += 1
        # If we want symmetric co-occurence can also increment for these.
        if symmetric:
           log co occurence[input[1], input[0]] += 1
           log co occurence[input[2], input[1]] += 1
           log co occurence[input[3], input[2]] += 1
    delta smoothing = 0.5  # A hyperparameter. You can play with this if you want.
    log_co_occurence += delta_smoothing  # Add delta so log doesn't break on 0's.
    log co occurence = np. log(log co occurence)
    return log co occurence
asym log co occurence train = calculate log co occurence(data['train inputs'], symmetric=False)
asym log co occurence valid = calculate log co occurence (data['valid inputs'], symmetric=False)
```

• TO BE IMPLEMENTED: Calculate the gradient of the loss function w.r.t. the parameters  $W, \tilde{W}, \mathbf{b}$ , and  $\mathbf{b}$ . You should vectorize the computation, i.e. not loop over every word.

```
def loss_GLoVE(W, W_tilde, b, b_tilde, log_co_occurence):
    "Compute the GLoVE loss."
    n,_ = log_co_occurence.shape
    if W_tilde is None and b_tilde is None:

```

### ullet 1.4. Effect of embedding dimension d [0pt]

Train the both the symmetric and asymmetric GLoVe model with varying dimensionality d by running the cell below. Comment on:

- 1. Which d leads to optimal validation performance for the asymmetric and symmetric models?
- 2. Why does / doesn't larger d always lead to better validation error?
- 3. Which model is performing better, and why?

#### 1.4 Answer: \*\*TODO: Write Part 1.4 answer here\*\*

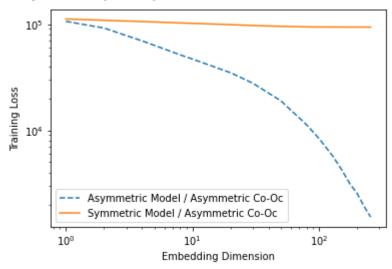

#### Train the GLoVE model for a range of embedding dimensions

```

### → Part 2: Network Architecture (2pts)

See the handout for the written questions in this part.

### Answer the following questions

### 2.1. Number of parameters in neural network model [1pt]

Assume in general that we have V words in the dictionary and use the previous N words as inputs. Suppose we use a D-dimensional word embedding and a hidden layer with H hidden units. The trainable parameters of the model consist of 3 weight matrices and 2 sets of biases. What is the total number of trainable parameters in the model, as a function of V, N, D, H?

In the diagram given, which part of the model (i.e., <code>word\_embbeding\_weights</code>, <code>embed\_to\_hid\_weights</code>, <code>hid\_to\_output\_weights</code>, <code>hid\_bias</code>, or <code>output\_bias</code>) has the largest number of trainable parameters if we have the constraint that  $V\gg H>D>N$ ? Note: The symbol  $\gg$  means ``much greater than" Explain your reasoning.

2.1 Answer: Let's find the number of the trainable parameters of the word embedding weights first. Since there are V words in the dictionary and the dimension of the word embedding layer is  $N \times D$ , we can get that there are  $V \times D$  trainable parameters.

For weights between the word embedding layer and the hidden layer, since there are H units in the hidden layer, the dimension of the matrix that connects two layers should be  $ND \times H$ , which is the number of trainable parameters.

Thus, for the biases of the hidden layer, there should be H imes 1 trainable parameters.

Similarly, since the output layer consists of V words, there are  $V \times H$  trainable parameters for weights between the hidden layer and the output layer.

Thus, for the biases of the output layer, there should be V imes 1 trainable parameters.

Since V is much larger than other variables, we only need to consider the part that depends on V.

Thus, we can get that weights between the hidden layer and the output layer,

 $hid_to_output_weights$ , has the largest number of trainable parameters since H>D.

### ▼ 2.2 Number of parameters in n-gram model [1pt]

Another method for predicting the next words is an n-gram model, which was mentioned in Lecture 3. If we wanted to use an n-gram model with the same context length N as our network, we'd need to store the counts of all possible (N+1)-grams. If we stored all the counts explicitly, how many entries would this table have?

2.2 Answer: For each gram, we can choose any word from V words. Thus, there are  $V^N$  number of combinations for the previous N words. For the prediction, since the output layer is a softmax

over the V words, there are V words. Thus, there are  $V^{N+1}$  entries in the n-gram model scale with N.

### ullet 2.3. Comparing neural network and n-gram model scaling [0pt]

How do the parameters in the neural network model scale with the number of context words N versus how the number of entries in the n-gram model scale with N? [0pt]

2.3 Answer: \*\*TODO: Write Part 2.3 answer here\*\*

### Part 3: Training the model (3pts)

We will modify the architecture slightly from the previous section, inspired by BERT \citep{devlin2018bert}. Instead of having only one output, the architecture will now take in N=4 context words, and also output predictions for N=4 words. See Figure 2 diagram in the handout for the diagram of this architecture.

During training, we randomly sample one of the N context words to replace with a <code>[MASK]</code> token. The goal is for the network to predict the word that was masked, at the corresponding output word position. In practice, this <code>[MASK]</code> token is assigned the index 0 in our dictionary. The weights  $W^{(2)} = \text{hid\_to\_output\_weights}$  now has the shape  $NV \times H$ , as the output layer has NV neurons, where the first V output units are for predicting the first word, then the next V are for predicting the second word, and so on. We call this as concatenating output uniits across all word positions, i.e. the (j+nV)-th column is for the word j in vocabulary for the n-th output word position. Note here that the softmax is applied in chunks of V as well, to give a valid probability distribution over the V words. Only the output word positions that were masked in the input are included in the cross entropy loss calculation:

There are three classes defined in this part: Params, Activations, Model. You will make changes to Model, but it may help to read through Params and Activations first.

$$C = -\sum_{i}^{B} \sum_{n}^{N} \sum_{j}^{V} m_{n}^{(i)}(t_{n,j}^{(i)} \log y_{n,j}^{(i)}),$$

Where  $y_{n,j}^{(i)}$  denotes the output probability prediction from the neural network for the i-th training example for the word j in the n-th output word, and  $t_{n,j}^{(i)}$  is 1 if for the i-th training example, the word j is the n-th word in context. Finally,  $m_n^{(i)} \in \{0,1\}$  is a mask that is set to 1 if we are

predicting the n-th word position for the i-th example (because we had masked that word in the input), and 0 otherwise.

There are three classes defined in this part: Params, Activations, Model. You will make changes to Model, but it may help to read through Params and Activations first.

```

```
idxs = np.random.permutation(inputs.shape[0])
inputs = inputs[idxs, :]

for m in range(num_batches):
    vield inputs[m * batch size:(m + 1) * batch size, :]
```

In this part of the assignment, you implement a method which computes the gradient using backpropagation. To start you out, the *Model* class contains several important methods used in training:

- compute\_activations computes the activations of all units on a given input batch
- compute\_loss computes the total cross-entropy loss on a mini-batch
- evaluate computes the average cross-entropy loss for a given set of inputs and targets

You will need to complete the implementation of two additional methods which are needed for training, and print the outputs of the gradients.

### 3.1 Implement gradient with respect to output layer inputs [1pt]

compute\_loss\_derivative computes the derivative of the loss function with respect to the output layer inputs.

In other words, if C is the cost function, and the softmax computation for the j-th word in vocabulary for the n-th output word position is:

$$y_{n,j} = rac{e^{z_{n,j}}}{\sum_l e^{z_{n,l}}}$$

This function should compute a  $B \times NV$  matrix where the entries correspond to the partial derivatives  $\partial C/\partial z_j^n$ . Recall that the output units are concatenated across all positions, i.e. the (j+nV)-th column is for the word j in vocabulary for the n-th output word position.

### 3.2 Implement gradient with respect to parameters [1pt]

back\_propagate is the function which computes the gradient of the loss with respect to model parameters using backpropagation. It uses the derivatives computed by *compute\_loss\_derivative*. Some parts are already filled in for you, but you need to compute the matrices of derivatives for <code>embed\_to\_hid\_weights</code>, <code>hid\_bias</code>, <code>hid\_to\_output\_weights</code>, and <code>output\_bias</code>. These matrices have the same sizes as the parameter matrices (see previous section).

In order to implement backpropagation efficiently, you need to express the computations in terms of matrix operations, rather than *for* loops. You should first work through the derivatives on pencil and paper. First, apply the chain rule to compute the derivatives with respect to individual units, weights, and biases. Next, take the formulas you've derived, and express them in matrix form. You

should be able to express all of the required computations using only matrix multiplication, matrix transpose, and elementwise operations --- no *for* loops! If you want inspiration, read through the code for *Model.compute\_activations* and try to understand how the matrix operations correspond to the computations performed by all the units in the network.

To make your life easier, we have provided the routine <code>checking.check\_gradients</code>, which checks your gradients using finite differences. You should make sure this check passes before continuing with the assignment.

```
class Model (object):
       """A class representing the language model itself. This class contains various meth
       the model and visualizing the learned representations. It has two fields:
                      a Params instance which contains the model parameters
              vocab, a list containing all the words in the dictionary; vocab[0] is the

### → 3.3 Print the gradients [1pt]

To make your life easier, we have provided the routine <code>check\_gradients</code>, which checks your gradients using finite differences. You should make sure this check passes before continuing with the

assignment. Once <code>check\_gradients()</code> passes, call <code>print\_gradients()</code> and include its output in your write-up.

```

### ▼ 3.4 Run model trainin [0pt]

Once you've implemented the gradient computation, you'll need to train the model. The function *train* implements the main training procedure. It takes two arguments:

- embedding\_dim: The number of dimensions in the distributed representation.
- num\_hid: The number of hidden units

As the model trains, the script prints out some numbers that tell you how well the training is going. It shows:

- The cross entropy on the last 100 mini-batches of the training set. This is shown after every 100 mini-batches.
- The cross entropy on the entire validation set every 1000 mini-batches of training.

At the end of training, this function shows the cross entropies on the training, validation and test sets. It will return a *Model* instance.

To convince us that you have correctly implemented the gradient computations, please include the following with your assignment submission:

- You will submit al-code. ipynb through MarkUs. You do not need to modify any of the code except the parts we asked you to implement.
- In your writeup, include the output of the function <code>print\_gradients</code>. This prints out part of the gradients for a partially trained network which we have provided, and we will check them against the correct outputs. **Important:** make sure to give the output of <code>print\_gradients</code>, **not** <code>check\_gradients</code>.

#### This is worth 4 points:

- 1 for the loss derivatives,
- 1 for the bias gradients, and
- 2 for the weight gradients.

Since we gave you a gradient checker, you have no excuse for not getting full points on this part.

## → Part 4: Arithmetics and Analysis (2pts)

In this part, you will perform arithmetic calculations on the word embeddings learned from previous

#### ▼ 4.1 t-SNE

You will first train the models discussed in the previous sections; you'll use the trained models for the remainder of this section.

**Important**: if you've made any fixes to your gradient code, you must reload the a1-code module and then re-run the training procedure. Python does not reload modules automatically, and you don't want to accidentally analyze an old version of your model.

These methods of the Model class can be used for analyzing the model after the training is done:

- tsne\_plot\_representation creates a 2-dimensional embedding of the distributed
  representation space using an algorithm called t-SNE. (You don't need to know what this is
  for the assignment, but we may cover it later in the course.) Nearby points in this 2-D space
  are meant to correspond to nearby points in the 16-D space.
- display\_nearest\_words lists the words whose embedding vectors are nearest to the given word
- word\_distance computes the distance between the embeddings of two words

Plot the 2-dimensional visualization for the trained model from part 3 using the method  $tsne\_plot\_representation$ . Look at the plot and find a few clusters of related words. What do the words in each cluster have in common? Plot the 2-dimensional visualization for the GloVe model from part 1 using the method  $tsne\_plot\_GLoVe\_representation$ . How do the t-SNE embeddings for both models compare? Plot the 2-dimensional visualization using the method  $plot\_2d\_GLoVe\_representation$ . How does this compare to the t-SNE embeddings? Please answer in 2 sentences for each question and show the plots in your submission.

#### 4.1 Answer:

According to Figure 1 (tsne\_plot\_representation), we can see that words with the similar function in sentences or the structure in terms of the speech gather together. For example, on the top left of the plot, there is a cluster of auxiliary verbs including "would", "could", and "should", and a cluster of question words such as "what", "how", and "who" on the middle left of the plot.

For Figure 1 and 2 (tsne\_plot\_GLoVE\_representation), we can see that words in Figure 1 are distributed like a linear on the main diagonal, while words in Figure 2 diverge circularly around the biggest cluster on the lower middle. In addition, we found that positions of different clusters are different in two plots.

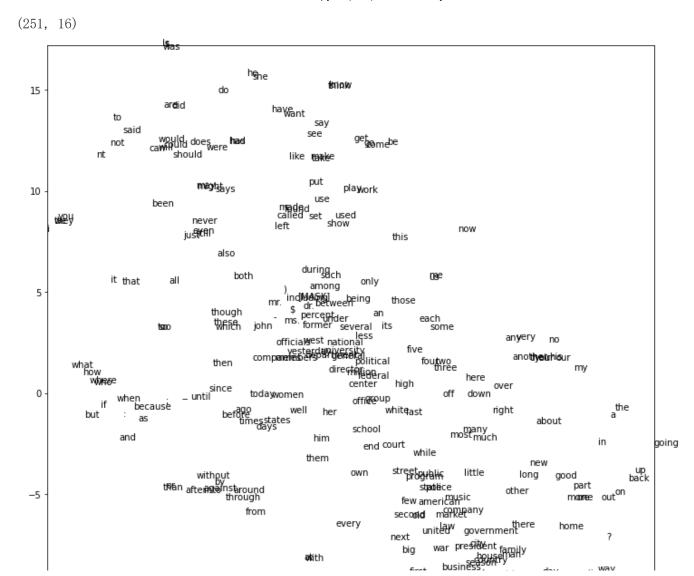

Comparing with Figure 1 and 2, we can see that words in Figure 3 (plot\_2d\_GLoVe\_representation)

seem to be more clustered and are distributed like a fan shape. Many nouns gather together on the

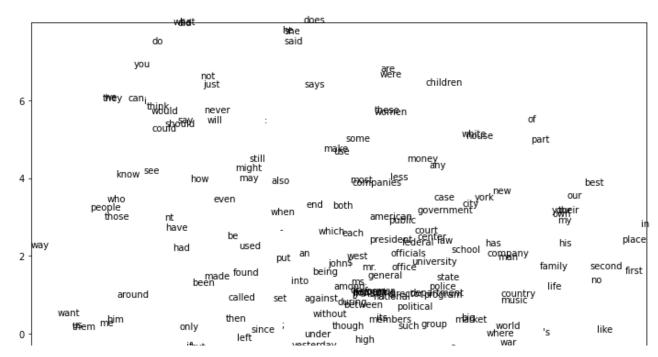

```
from sklearn.manifold import TSNE
def tsne plot representation (model):
       """Plot a 2-D visualization of the learned representations using t-SNE."""
       print(model.params.word embedding weights.shape)
       mapped X = TSNE(n components=2).fit transform(model.params.word embedding weights)
       pylab. figure (figsize=(12, 12))
       for i, w in enumerate (model. vocab):
               pylab.text(mapped X[i, 0], mapped X[i, 1], w)
       pylab.xlim(mapped X[:, 0].min(), mapped X[:, 0].max())
       pylab.ylim(mapped X[:, 1].min(), mapped X[:, 1].max())
       pylab. show()
def tsne plot GLoVE representation(W final, b final):
       """Plot a 2-D visualization of the learned representations using t-SNE."""
       mapped X = TSNE(n components=2).fit transform(W final)
       pylab. figure (figsize=(12, 12))
       data obj = pickle.load(open(data location, 'rb'))
       for i, w in enumerate(data obj['vocab']):
               pylab.text(mapped X[i, 0], mapped X[i, 1], w)
       pylab.xlim(mapped X[:, 0].min(), mapped X[:, 0].max())
       pylab.ylim(mapped X[:, 1].min(), mapped X[:, 1].max())
       pylab. show()
def plot 2d GLoVE representation(W final, b final):
       """Plot a 2-D visualization of the learned representations."""
       mapped X = W final
       pylab. figure (figsize=(12, 12))
       data_obj = pickle.load(open(data location, 'rb'))
       for i, w in enumerate(data obj['vocab']):
               pylab.text(mapped X[i, 0], mapped X[i, 1], w)
       pylab.xlim(mapped X[:, 0].min(), mapped X[:, 0].max())
       pylab. vlim (mapped X[:, 1].min(), mapped X[:, 1].max())
       pylab. show()
```

tsne\_plot\_GLoVE\_representation(W\_final\_2d, b\_final\_2d)

### ▼ 4.2 Word Embedding Arithmetic

A word analogy f is an invertible transformation that holds over a set of ordered pairs S iff  $\forall (x,y) \in s, f(x) = y \land f^{-1}(y) = x$ . When f is of the form  $\overrightarrow{x} \to \overrightarrow{x} + \overrightarrow{r}$ , it is a linear word analogy.

Arithmetic operators can be applied to vectors generated by language models. There is a famous example:  $\overrightarrow{king} - \overrightarrow{man} + \overrightarrow{women} \approx \overrightarrow{queen}$ . These linear word analogies form a parallelogram structure in the vector space (Ethayarajh, Duvenaud, & Hirst, 2019).

In this section, we will explore a property of *linear word analogies*. A linear word analogy holds exactly over a set of ordered word pairs S iff  $\|\overrightarrow{x} - \overrightarrow{y}\|^2$  is the same for every word pair,  $\|\overrightarrow{a} - \overrightarrow{x}\|^2 = \|\overrightarrow{b} - \overrightarrow{y}\|^2$  for any two word pairs, and the vectors of all words in S are coplanar.

We will use the embeddings from the symmetric, asymmetrical GloVe model, and the neural network model from part 3 to perform arithmetics. The method to perform the arithmetic and retrieve the closest word embeddings is provided in the notebook using the method find word analogy:

 find\_word\_analogy returns the closest word to the word embedding calculated from the 3 given words.

```
You can play with this if you want.
erparameter.
sym, W final asym = None,
                             None,
                                    None
 hyperparameter.
                    You can play with this if you want.
ndom.normal(size=(vocab size,
                             embedding dim))
 np. random. normal (size=(vocab size,
                                    embedding dim))
ndom.normal(size=(vocab size, 1))
 np. random. normal(size=(vocab size,
                                   1))
                                           None, asym log co occurence train, asym log co occurer
               = train GLoVE(W, None, b,
```

```
_asym, b_final_asym, b_tilde_final_asym, _, _ = train_GLoVE(W, W_tilde, b, b_tilde, asym_log_
```

You will need to use different embeddings to evaluate the word analogy

```
def get word embedding (word, embedding weights):
       assert word in data['vocab'], 'Word not in vocab'
       return embedding weights[data['vocab'].index(word)]
\# word4 = word1 - word2 + word3
def find word analogy (word1, word2, word3, embedding weights):
       embedding1 = get word embedding(word1, embedding weights)
       embedding2 = get word embedding (word2, embedding weights)
       embedding3 = get word embedding(word3, embedding weights)
       target embedding = embedding1 - embedding2 + embedding3
       # Compute distance to every other word.
       diff = embedding weights - target_embedding.reshape((1, -1))
       distance = np.sqrt(np.sum(diff ** 2, axis=1))
       # Sort by distance.
       order = np. argsort (distance) [:10]
       print("The top 10 closest words to emb({}) - emb({}) + emb({}) are:".format(word1,
       for i in order:
               print('{}: {}'.format(data['vocab'][i], distance[i]))
```

In this part of the assignment, you will use the find\_word\_analogy function to analyze quadruplets from the vocabulary.

#### 4.2.1 Specific example

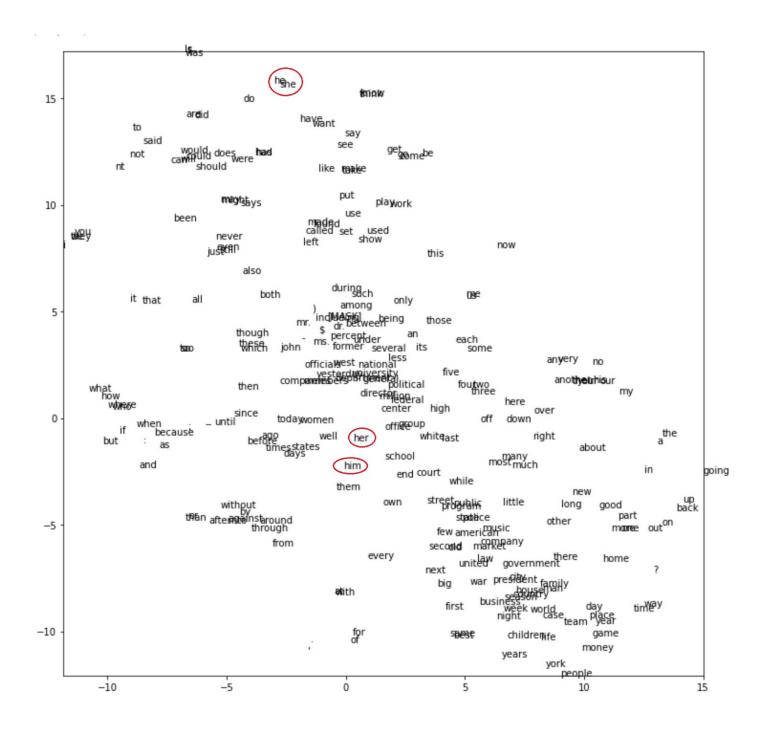

Perform arithmetic on words *her*, *him*, *her*, using: (1) symmetric, (2) averaging asymmetrical GloVe embedding, (3) concatenating asymmetrical GloVe embedding, and (4) neural network word embedding from part 3. That is, we are trying to find the closet word embedding vector to the vector

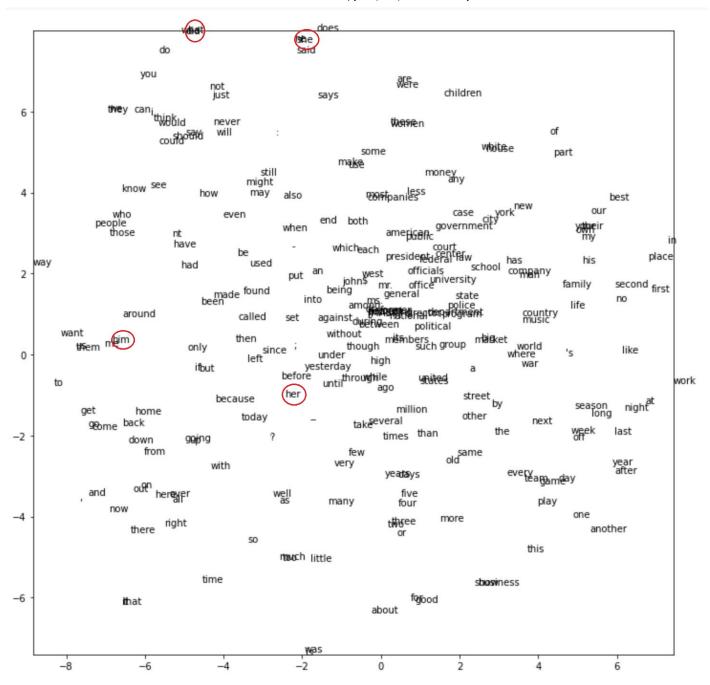

$$emb(he)-emb(him)+emb(her)$$

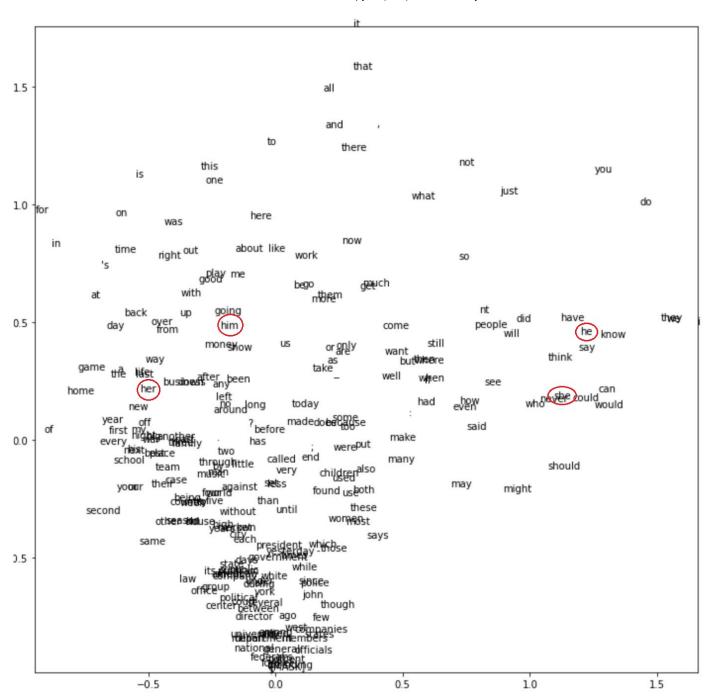

For each sets of embeddings, you should list out: (1) what the closest word that is not one of those three words, and (2) the distance to that closest word. Is the closest word *she*? Compare the results with the tSNE plots.

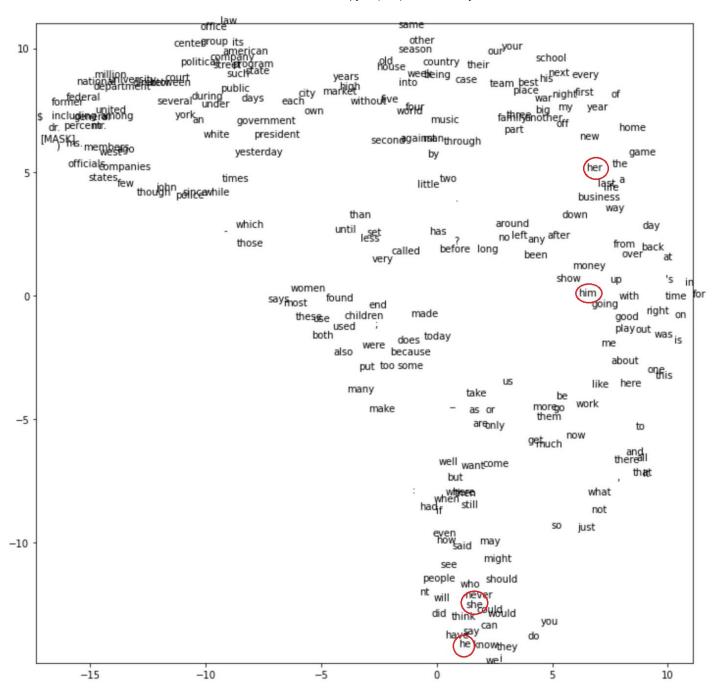

4.2.1 **Answer**: According to the outputs, we can see that the closest word that are not "he", "him", and "her" is "she" for all 4 different arithmetic. The corresponding distances are shown below.\

According to four plots, they all show the parallelogram property of the quadruplets approximately. The following graphs show how they present for each corresponding plot.

```
## GloVe embeddings
embedding_weights = W_final_sym # Symmetric GloVe
find_word_analogy('he', 'him', 'her', embedding_weights)
